

① To find three planes in 3-D space that are pairwise orthogonal (perpendicular) & intersect at $(5, 7, 4) \in \mathbb{R}^3$

Let consider three normal vectors \vec{n}_1, \vec{n}_2 & \vec{n}_3 & the point of intersection as $P(5, 7, 4) = (a, b, c)$

Since, it is given ~~as~~ that the planes are pairwise orthogonal, so, the dot products between the normal vectors are zero.

$$\text{i.e., } \vec{n}_1 \cdot \vec{n}_2 = 0$$

$$\vec{n}_1 \cdot \vec{n}_3 = 0$$

$$\vec{n}_2 \cdot \vec{n}_3 = 0$$

* for plane 1; Consider a simple plane whose normal vector is along x-axis.

$$\text{normal vector } \vec{n}_1 = (1, 0, 0) = (A, B, C)$$

from point-normal equation.

$$A(x-a) + B(y-b) + C(z-c) = 0.$$

$$1(x-5) + 0 + 0 = 0$$

$$x - 5 = 0$$

\therefore Equation of plane 1 is $x - 5 = 0$.

* for plane $(1, 0, 0)$ is taken as the normal vector because, any non zero vector that is orthogonal (perpendicular) to the plane can be considered as the normal vector.

* for plane 2; we need to consider a normal vector that is orthogonal to $\vec{n}_1 = (1, 0, 0)$ and along the y-axis.

normal vector $\vec{n}_2 = (0, 1, 0) = (A, B, C)$

from point-normal equation,

$$A(x-a) + B(y-b) + C(z-c) = 0$$

$$0 + 1(y-7) + 0 = 0$$

$$y-7=0$$

\therefore Equation of plane 2 is $y-7=0$

* for plane 3, we need to consider a normal vector that is orthogonal to $\vec{n}_1 = (1, 0, 0)$ & $\vec{n}_2 = (0, 1, 0)$ and along z-axis.

~~we~~ take the ~~for~~ cross product of \vec{n}_1 & \vec{n}_2 to get \vec{n}_3 .

$$\vec{n}_3 = \vec{n}_1 \times \vec{n}_2$$

$$\vec{n}_3 = (1, 0, 0) \times (0, 1, 0)$$

$$\vec{n}_3 = (0, 0, 1) = (A, B, C)$$

from point-normal equation,

$$0 + 0 + 1(z-4) = 0$$

$$z-4=0$$

\therefore The equation of plane 3 is $z-4=0$

\therefore the equations are: $x-5=0$, $y-7=0$

$$\text{& } \underline{\underline{z-4=0}}$$

- ② If the component function of a parametric curve
a) are linear, then the parametric curve describes
a straight line in space.

The above statement is true.

If the component function of a parametric curve
are linear, each component has the form

$$f(t) = At + B, \quad g(t) = Ct + D, \quad h(t) = Et + F$$

when these ~~for~~ linear components are used as the
components of a parametric curve

$\vec{r}(t) = \langle f(t), g(t), h(t) \rangle$ the resulting curve
is a straight line.

~~the symmetric equation of a line is given by.~~

the combination of all three linear equations
describes a straight line in 3-D space.

- b) If a parametric curve describes a straight line
in space, then its component functions are
linear.

The above statement is false. As previously
we saw it is true that a parametric curve with
linear ~~for~~ component function describes a
straight line in space, the vice-versa may not
be necessarily true because the parametric
curve that describes a straight line in space can
have a non-linear components functions.

such as $\vec{r}(t) = \langle t^2, t^3, t \rangle$.

a straight line ~~has~~ has slope equal to zero but the component functions are quadratic & cubic with different slopes.

c) If the component functions of a parametric curve are quadratic, then the parametric curve describes a parabola in space.

The Above Statement is True. Each component function has form $f(t) = At^2 + Bt + C$,

$$g(t) = Dt^2 + Et + F \text{ \& \; } h(t) = Gt^2 + Ht + I$$

in the parametric curve $\vec{r} = \langle f(t), g(t), h(t) \rangle$

where, $A, B, C, D, E, F, G, H, \& I$ are constants.

the resulting curve is a parabola in

3-D space. Here, Each components quadratic

equation represents the point's position on the parabola as function of 't'.

$$\langle f(t), g(t), h(t) \rangle = (t)^2 \text{ \& \; } (t)^2 \text{ \& \; } (t)^2$$

③ To find the tangent line to the parametric curve $\vec{r}(t) = \langle \cos t, t+1, \sin t \rangle$ at the point $(1, 1, 0)$.

derivative of $\vec{r}(t)$ is

$$\vec{r}'(t) = \langle -\sin t, 1, \cos t \rangle$$

to find the value of t :

we know, $\vec{r}(t) = \langle \cos t, t+1, \sin t \rangle$

$$\text{equates } \vec{r}(t) = (1, 1, 0)$$

$$\text{So, } \cos t = 1$$

$$t+1 = 1$$

$$\sin t = 0$$

solving for t from the above equation,

$$\cos t = 1 \Rightarrow t = 0$$

$$t+1 = 1 \Rightarrow t = 0$$

$$\sin t = 0 \Rightarrow t = 0$$

Evaluating $\vec{r}(t)$ & $\vec{r}'(t)$ at $t = 0$

$$\vec{r}(0) = \langle \cos 0, 0+1, \sin 0 \rangle = (1, 1, 0)$$

$$\vec{r}'(0) = \langle -\sin 0, 1, \cos 0 \rangle = (0, 1, 1)$$

Equation of the tangent line in vector form, can be written using $\vec{r}(0)$ & $\vec{r}'(0)$

$$\vec{L}(t) = \vec{r}(0) + t \vec{r}'(0)$$

Substitute the values of $\vec{r}(0)$ & $\vec{r}'(0)$

$$\vec{L}(t) = (1, 1, 0) + t(0, 1, 1)$$

$$\vec{L}(t) = (1, 1+t, t)$$

So, the equation of the tangent line to the parametric curve $\vec{r}(t) = (\cos t, t+1, \sin t)$ at point $(1, 1, 0)$ is given by

$$\vec{L}(t) = (1, 1+t, t)$$

where, $x(t) = 1$, $y(t) = 1+t$ & $z(t) = t$.

$$(0, 1, 1) = (t) \vec{v}$$

$$1 = t \cos t$$

$$1 = 1+t$$

$$0 = t \sin t$$

$$0 = t \Rightarrow 1 = t \cos t$$

$$0 = t \Rightarrow 1 = 1+t$$

$$0 = t \Rightarrow 0 = t \sin t$$

$$0 = t \Rightarrow (t) \vec{v} = (t) \vec{v}$$

$$(0, 1, 1) = \langle \cos t, t+1, \sin t \rangle = (t) \vec{v}$$

$$(1, 1, 0) = \langle \cos t, t+1, \sin t \rangle = (t) \vec{v}$$

Equation of the tangent line in vector form can be written as

$$(t) \vec{r} + (t) \vec{v} = (t) \vec{v}$$

$$(t) \vec{r} + (t) \vec{v} = (t) \vec{v}$$

$$(1, 1, 0) + (t) \vec{v} = (t) \vec{v}$$

$$(1, 1, 0) = (t) \vec{v}$$

④ given two parametric curves

$$\vec{r}(t) = \langle t, 1+2t, 3-2t \rangle$$

$$\vec{s}(t) = \langle -2-2t, 1-2t, 1+t \rangle$$

- a) To check for collision of the points, we need to equate the points of the two curves, then solve for 't'. If there are values of 't' that make both equation true, then the two points collide else they do not collide.

Now, let equate the curve's components & check for collision

$$t = -2-2t, \quad 1+2t = 1-2t, \quad 3-2t = 1+t.$$

$$3t = -2, \quad 4t = 0, \quad 3t = 2$$

$$\boxed{t = -\frac{2}{3}}, \quad \boxed{t = 0}, \quad \boxed{t = \frac{2}{3}}$$

So, there are ^{no} values of t where the positions of 2 points are equal ~~irrespective of their magnitude~~.

Hence, the points do ^{not} collide at ^{any of} the above mentioned time instances.

- b) To check for crossing of their paths, equate the components of the curves, then solve for 't'

If there are value of 't' where the position of two curves are equal, then the paths cross else they do not cross.

here, we found out 't' values to be

$$t = -\frac{2}{3}, t = 0, t = \frac{2}{3}$$

therefore, their paths also do not cross, as they never occupy the same point simultaneously in all three dimensions

which also means that the two paths do not cross

hence, the two paths do not cross

$$t = -\frac{2}{3}$$

$$t = 0$$

$$t = \frac{2}{3}$$

$$t = -\frac{2}{3}$$

$$t = 0$$

$$t = \frac{2}{3}$$

$$t = -\frac{2}{3}$$

$$t = 0$$

$$t = \frac{2}{3}$$

hence, the two paths do not cross
therefore, the two paths do not cross
hence, the two paths do not cross

hence, the two paths do not cross

hence, the two paths do not cross

hence, the two paths do not cross

hence, the two paths do not cross

hence, the two paths do not cross
